# **Draft Analyzer**

# 1. Modeling

# 1.1. Defining Items and Objects

Let us define a champion by an ID: each champion has a unique ID between 1 and 170 (since there are currently 170 champions).

Let us define the Victory-Defeat matrix  $M \in M_{170}(\mathbb{N})$ .

For  $(i, j) \in [1; 170]^2$ , the coefficient  $M_{i,j}$  represents the number of victories of champion i over the champion j.

Consequently we can have the number of win  $w_i \in \mathbb{N}$  and the number of loose  $l_i \in \mathbb{N}$ .

$$w_i = \frac{\sum_{k=1}^{170} M_{i,k}}{5}$$

$$l_i = \frac{\sum_{k=1}^{170} M_{k,i}}{5}$$

 $w_i$  will be the sum of the line i and  $l_i$  will be the sum of the column i. We will explain later why these sums are divided by 5.

#### 1.2. Draft

What is a draft ? A draft is the selection of 5 champions against 5 others champions, all of which are distinct. Mathematically, we can define a draft as a 10-tuple, denoted by D:

$$D = (x_1, x_2, x_3, x_4, x_5, x_5, x_6, x_7, x_8, x_9, x_{10})$$
 
$$\forall (i, j) \in \llbracket 1, 10 \rrbracket \text{ we have}: \ x_i \neq x_j$$

The draft is divided into two teams: the "Red" team and the "Blue" team. We can define these teams as two 5 —tuple: R and B:

$$R = (x_1, x_2, x_3, x_4, x_5)$$
  
$$B = (x_5, x_6, x_7, x_8, x_9, x_{10})$$

And finnally after a match one of the two team win and the other team loose and we need to update M.

After a match, one team wins and the other loses, and we update the matrix M accordingly. For each victorious champion, we add 1 to each column corresponding to the defeated champions of the opposing team. Since there are 5 champions on each team, this explains why we divide by 5 when calculating the number of wins and losses.

### 1.3. Probability

Now let's create your model to calculate probability of win of the "Red" or "Blue" with the history of the last match.

First define define the "Strength of a champion" called  $S_i$ :

$$S_i = \sum_{k=1}^5 \left( \left( \frac{w_{x_k}}{w_{x_k} + l_{x_k}} \right) \frac{1}{3} + \left( \frac{M_{i,k}}{M_{i,k} + M_{k,i}} \right) \frac{2}{3} \right)$$

Lets add details about  $S_i$ :

• *i* is the indice of the champion in draft.

- $x_i$  is the indice of the chmapion in the oppenent team for  $i \in [1, 5]$ .
- $\frac{1}{3}$  and  $\frac{2}{3}$  are weights for the general win probability and for the direct matchup.

Now we can define the "Strength of team" for the "Red" and for the "Blue" :  $S_R$  and  $S_B$ 

$$S_t = \sum_{k=1}^5 S_k$$

with  $t \in \{R, B\}$ 

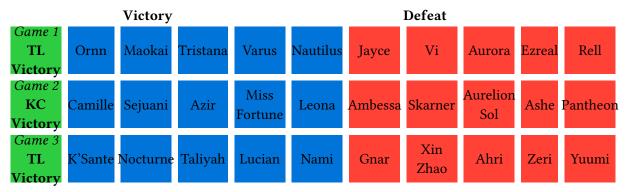

Now lets use the logistic function to have the probabilty of winnig of one side :

$$\mathbb{P}_{\!R} = \frac{1}{1+e^{-(S_R-S_B)}}$$

# 2. Historical of draft and command in Prolog

initialiser(Matrix).

#### 2.1. KC - TL:

Add victory in matrix of the match:

```
add_victory('Ornn','Maokai','Tristana','Varus','Nautilus','Jayce','Vi','Aurora','Ezreal','Rell').
add_victory('Camille','Sejuani','Azir','Miss
Fortune','Leona','Ambessa','Skarner','Aurelion Sol','Ashe','Pantheon').
add_victory('K\'Sante','Nocturne','Taliyah','Lucian','Nami','Gnar','Xin
Zhao','Ahri','Zeri','Yuumi').
```

### 2.2. TES - HLE

#### 2.2.1. Calcul of winnig proba of the draft

**TES-HLE** 

### 2.2.2. Draft TES - HLE with victory

Victory Defeat

Game 1 HLE Victory	Jax	Skarner	Azir	Ezreal	Alistar	Kennen	Vi	Aurora	Miss Fortune	Leona
Game 2 HLE Victory	Aatrox	Nidalee	Akali	Varus	Poppy	Gragas	Nocturne	Orianna	Kalista	Renata Glasc

add\_victory('Jax','Skarner','Azir','Ezreal','Alistar','Kennen','Vi','Aurora','Miss
Fortune','Leona').

add\_victory('Aatrox','Nidalee','Akali','Varus','Poppy','Gragas','Nocturne','Orianna','Kalista','Ren
Glasc').
